EXECUTIVE SUMMARY
2011 Nova Scotia Offshore: Play Fairway Analysis
New Geoscience – New Opportunity

Introduction
The history of petroleum exploration in Nova Scotia’s offshore spans more than 50 years. During this period, more than 200 exploration, delineation and production wells have been drilled with discoveries in place reserves ~2.1 Bbbls (billion barrels of oil equivalent). Recent exploration has not been successful. Since 1998, a total of 29 wells have been drilled at a cost of over $1 billion, but with only one commercial gas discovery, Deep Panuke in 1998. The lack of recent exploration drilling success is reflected in the decline in exploration licenses, from a high of 59 in 2002 to only 10 in early 2008, most of which have now been relinquished.

Strategy to Attract Exploration Investment
In 2007, the Nova Scotia Department of Energy commissioned a number of studies to investigate the reasons for the decline in exploration, with an objective of designing a strategy to reinvigorate exploration interest in the offshore. These studies concluded that the region has a perception of being a high cost environment associated with high geological risk.

In 2008, the Government of Nova Scotia committed funding of approximately $18 million to the OETR Association (OETR) to enable it to undertake research to support offshore energy development. A significant portion of this (in the order of $15 million) funded the Play Fairway Analysis (PFA) program, with the goal of stimulating renewed offshore petroleum exploration activity.

The Play Fairway Analysis Project
In April 2009, OETR awarded a contract to RPS Energy of the United Kingdom to manage an industry standard Play Fairway Analysis project for offshore Nova Scotia. The objective of the project is to demonstrate to the industry that there is a commercially attractive hydrocarbon province offshore Nova Scotia.

The core interpretation work and analysis was awarded to Beicip-Franlab. In August 2009, Beicip-Franlab also integrated results from a number of special projects. The project recognized that there was a vast amount of knowledge about the offshore geology in Halifax, and it was important to incorporate this knowledge into the overall ‘Play Fairway’ story. The project was therefore split into a number of components in which the Halifax research community was able to contribute their specific technical expertise into an integrated geoscience analysis.

These special projects were combined into an integrated play fairway review. An extensive data base was used as the foundation of the project. This included some 70,000 km of 2D seismic and ~30,600 sq km of 3D. Of particular note are the ‘20 key wells’. The stratigraphy of these wells was re-constructed from a full biostratigraphic analysis. The wells were tied to a set of 2D Bible Lines’ from TGS and GKT. These lines were reprocessed to further enhance the imaging. Of critical importance was the ability to tie the stratigraphy from the slope onto the shelf.

Scale of the Oil and Gas Opportunity: Nova Scotia Offshore
The Play Fairway Analysis project has identified rich hydrocarbon potential offshore Nova Scotia, with unrisked 120 TCF of gas and 8 Billions of oil in place. This potential has diverse characteristics and scales. In present day shallow water, there is a substantial opportunity for traps with potential for both oil and gas. The shallow water depth makes this attractive to a wide range of oil companies, and this opportunity is relatively straightforward to explore.

The PFA has also identified and mapped very large-scale potential traps that could contain gas, condensate and/or oil in present day deepwater. The major innovative result of the work is the prediction of a substantial oil play in the southeast of the margin (Zones 1 & 2). Using conservative parameters, ~3.3 Billion of oil in place are predicted in this area (because of the methodology used for this assessment, this figure is likely to be an underestimate). Large-scale gas/condensate opportunities also exist in the proven Late Jurassic and Early Cretaceous clastic plays in the northeast part of the margin in deep water (Zones 3, 4, 5 & 6). These plays in deep water will be of interest to the large oil majors, who have the capability and capacity to operate in this challenging environment.

Key Conclusions
There are four important insights arising from the work. Three conclusions address the geological risk and the final, fourth, conclusion concerns the potential for hydrocarbon volumes.

Source Rocks
The PFA has developed a model that allows the potential for a regional Lower Jurassic oil prone (Type II) source rock that extends beyond the Sable Sub-basin and underlies the whole margin. The presence of this regional source rock is confirmed by isotope and molecular analyses of the oils discovered in piston cores taken along the length of the margin and supported by evidence from offset locations around the conjugate margin system. Analysis of these oils prove the presence of a distinct separate regional source rock. The presence of oil in the piston cores suggests that the source rock is oil prone in the Western half of the Scotian Margin. The eastern half is gas dominated, as demonstrated by the existing production, although with the potential of an oil rim round the Sable Sub-basin.

Executive Summary
Reservoir Rocks
The presence of reservoir rocks in the Sable area is proven. Detailed sequence stratigraphy, along with seismic analysis, has developed predictive models for four reservoirs that form the main play fairways for the margin:
- Mic Mac, Upper Jurassic Delta sequence in the northeast of the margin.
- Baccaro carbonate bank forms the reservoir for the Deep Panuke Field. This reservoir extends to the west along the 'shelf edge'.
- Two Lower Cretaceous Delta sequences are the producing reservoirs in the Sable Sub-basin. The PFA has developed a model to predict reservoir distribution in the Sable region itself, and with the use of sediment distribution models, combined with seismic attributes, can predict reservoir into the deep offshore as well as further west and east along the margin (Huron Sub-basin; see location Map - Zone 5).

Note that Logan Canyon and Wyandot reservoirs were not included in the present study.

These four play fairways are proven, and with the revised source rock model and de-risking approach are considered attractive. In addition to these plays, the PFA has identified untested reservoirs in the western part of the basin in the area of the oil prone source rock.

Petroleum Systems Modeling
The 3D petroleum systems model identifies target areas by determining source rock type and maturity at the present day. The following two statements can be made as a result of this modeling:

1. The Lower Jurassic source rock is generating oil today in the southwest part of the margin. In the eastern part of the margin, it want through the hydrocarbon generation zone earlier and is over mature at present day.
2. The main source rocks for the Sable Sub-basin fields is the upper Jurassic Tithonian sequence and is in the gas window today. The basin shallow at the margins and in the shallow region of the basin the source rock is in the oil window. Therefore, there is the potential for an 'oil rim' around the Sable delta and Huron Sub-basin. This is a credible oil play, which exists in shallow water and is under-explored.

Yet to Find and Prospect Sizes
The confident identification of two major source rock systems (deltaic and restricted marine) enables an assessment of the volumes of hydrocarbons generated. The modeling work indicates an unrisked 120 TCF of gas and 8 Bbls of oil in-place. The volumes of generated hydrocarbons are substantial and sufficient to fill large structures that can be seen on the seismic data.

Exploration Sweet Spots
The Composite Common Risk Segment (CCRS) mapping exercise has highlighted the following prospective areas.

Mature and Shelf Exploration
1. The Sable Sub-basin has significant remaining ‘Yet To Find’. The Upper Jurassic and Lower Cretaceous deltas are prospective in this region. A number of relatively small undrilled dip closed features are in the vicinity of the existing infrastructure.
2. The main Sable plays extend to the east of the Sable Sub-basin and extends to the Nova Scotia/Newfoundland border (Huron Sub-basin). The area is under explored with most of the wells drilled in the 1970s on poor quality 2D data.
3. The Baccaro carbonate bank and clastics also form attractive plays to the west of Sable where they would be sourced by the oil prone Pleistocene source rock.

### Age
- **Middle Jurassic**
  - Mohican
  - Baccaro

- **Upper Jurassic**
  - Mic Mac

- **Berrissian**
  - Lower Mississauga

- **Valanginian**
  - Middle Mississauga

- **Barremian**
  - Upper Mississauga

- **Aptian**
  - Logan Canyon

- **Albian**
  - Low stand

### Zone
- **Zone 1**
- **Zone 2**
- **Zone 3**
- **Zone 4**
- **Zone 5**
- **Zone 6**

Deep Water and Frontier Exploration
1. The PFA has identified the exciting possibility of an oil play in deep water in the southwest of the margin. The area is underlain by the postulated Lower Jurassic source rock, which is in the oil window today. Reservoirs are provided by Lower Cretaceous turbidite sands that are seen on the seismic and are predicted by facies modeling.
2. The deep water of the Sable Delta and to the northeast is more gas prone, but contains significant undrilled features. The presence of a non-commercial gas discovery (Annapolis) shows that the play works. The PFA has developed models to de-risk reservoir distribution in this area using seismic attributes.

Key Play Risks
A summary of the plays and their play risks is shown in the table below. This analysis shows each play sequence in terms of gross environment (delta top, delta front, etc.) and by geographic zones. It is clear that the lowest risk plays are in Zones 3 and 5 where the system is proven. The oil prone Zones 1 and 2 are shown as moderate risk, as they rely on existence of the predicted Early Jurassic marine source rock (likely to be low risk) and secondly, the ability to locate reservoirs in the southwest.

The PFA has demonstrated that there is significant potential that remains untapped offshore Nova Scotia (~120 TCF of gas and 9 Bbls of oil in place and unrisked) that warrants the attention of industry.
